

# A One-Hour DE Application on the TI NSpire

Jeff Kallenbach  
Tim Husband

Siena Heights University

# Background

---

- ▶ We use technology throughout the program
  - ▶ Smartboard for presentations
  - ▶ TI NSpire CAS is handheld of choice
    - ▶ Supplements, enrichment, checking, rote tasks
  - ▶ Maple for the heavier work

# TI Value-added

---

- ▶ Product is maintained well (software)
- ▶ TI is popular
- ▶ As such it has
  - ▶ Large collection of pre-fab activities
  - ▶ Partners and peripherals

# Highlights of the DE I Course

---

- ▶ Applications of previous work
- ▶ Applied Math
- ▶ Writing
- ▶ Maple as a tool

# Newton's Law Of Cooling

---

- ▶ Newton's Law

$$T'(t) = k(A - T)$$

- ▶ Prerequisites

- ▶ About 2-3 weeks of DE I
- ▶ Integration of  $\ln$  form

- ▶ Result

- ▶ Exponential growth/decay

# The Experiment

---

## ▶ Setup

- ▶ TI Emulator Software & Smartboard, or handheld
- ▶ Bucket of ice
- ▶ Three vials of liquid with different cooling constants, at room temp
- ▶ Three-port temperature probe – Vernier/Easy Link
- ▶ Writing tool (Latex/Word & MathType/...)
- ▶ One 50-min class period

# The Process

---

- ▶ Bring your medium to  $0^{\circ}C$
- ▶ Check and record the ambient temp  $A$
- ▶ Press the button to start the collection
- ▶ Dunk the solutions

# The Process

---

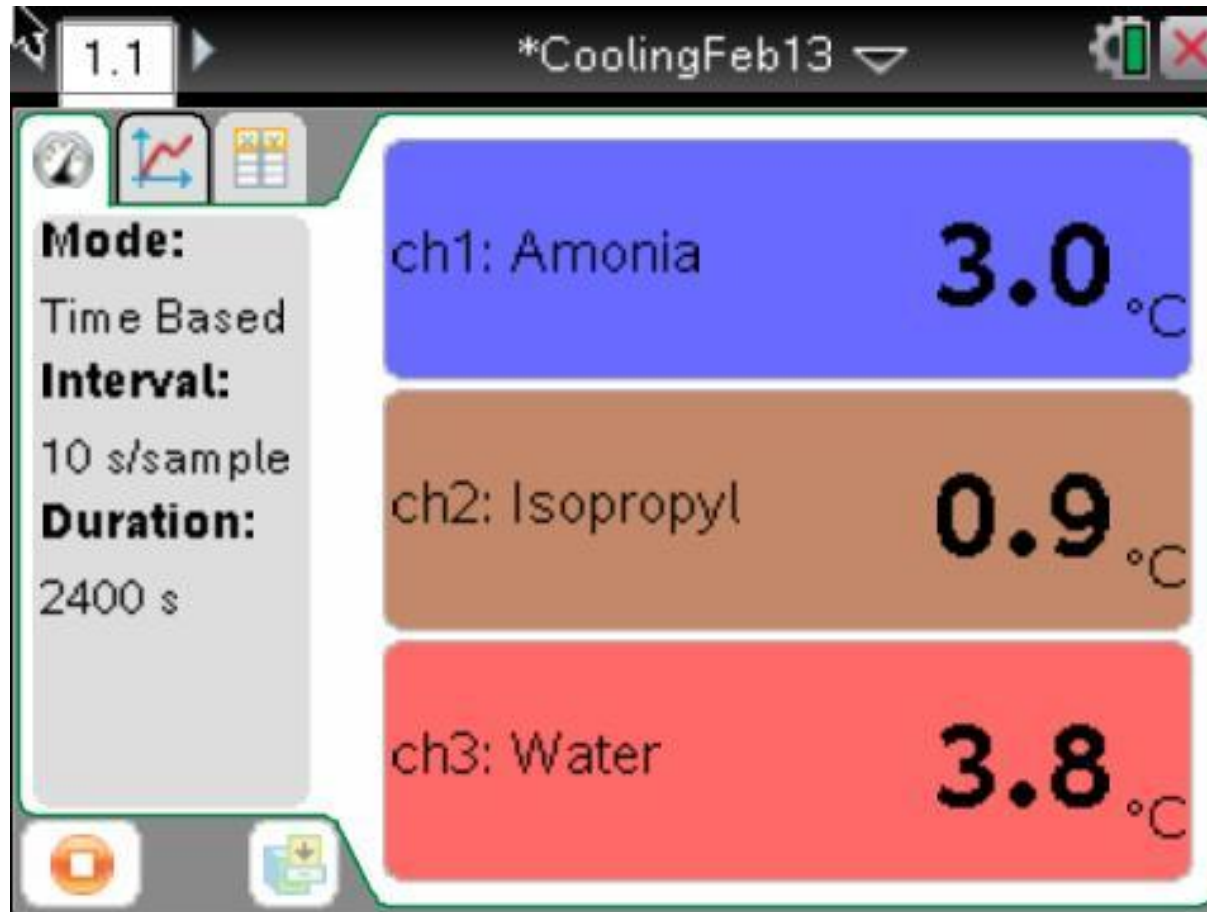

# The Setup With Computer

---

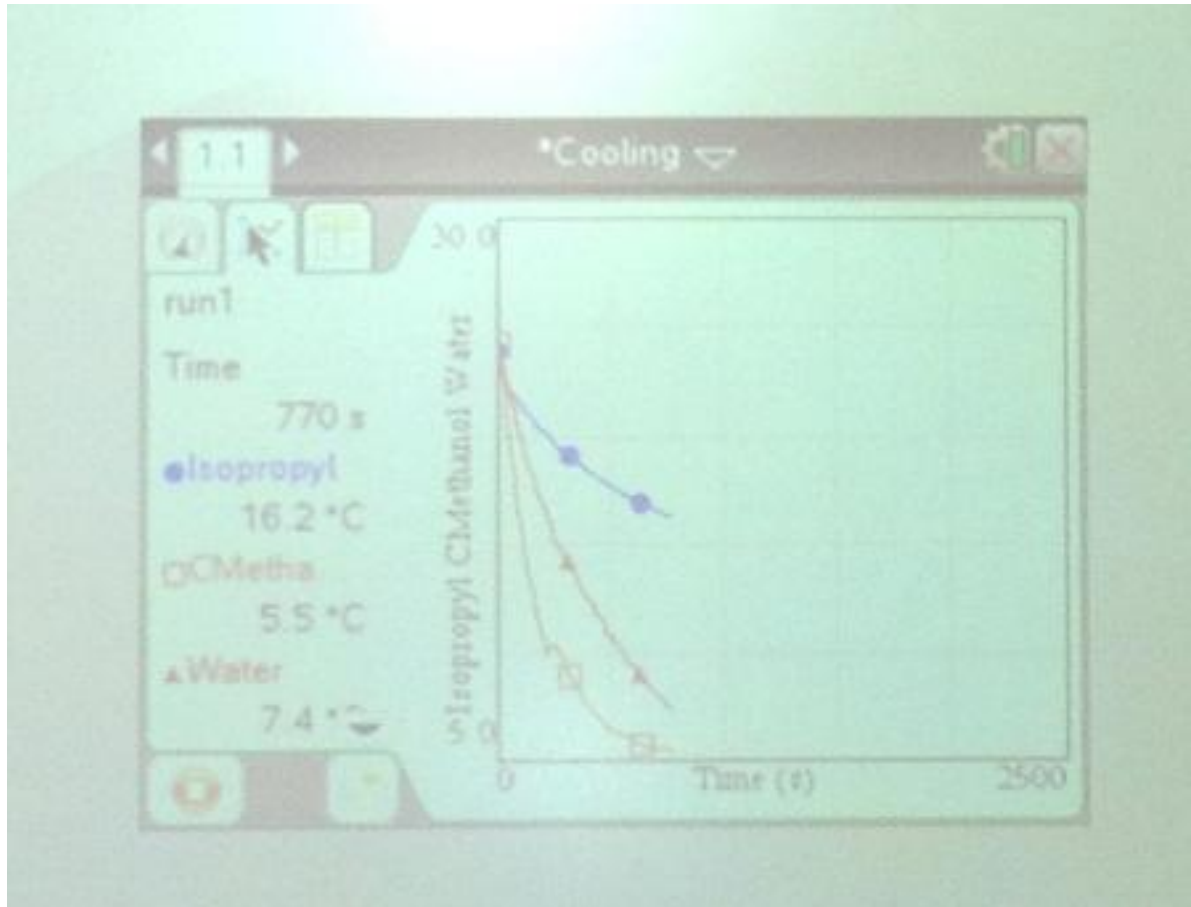

# Progress Reports

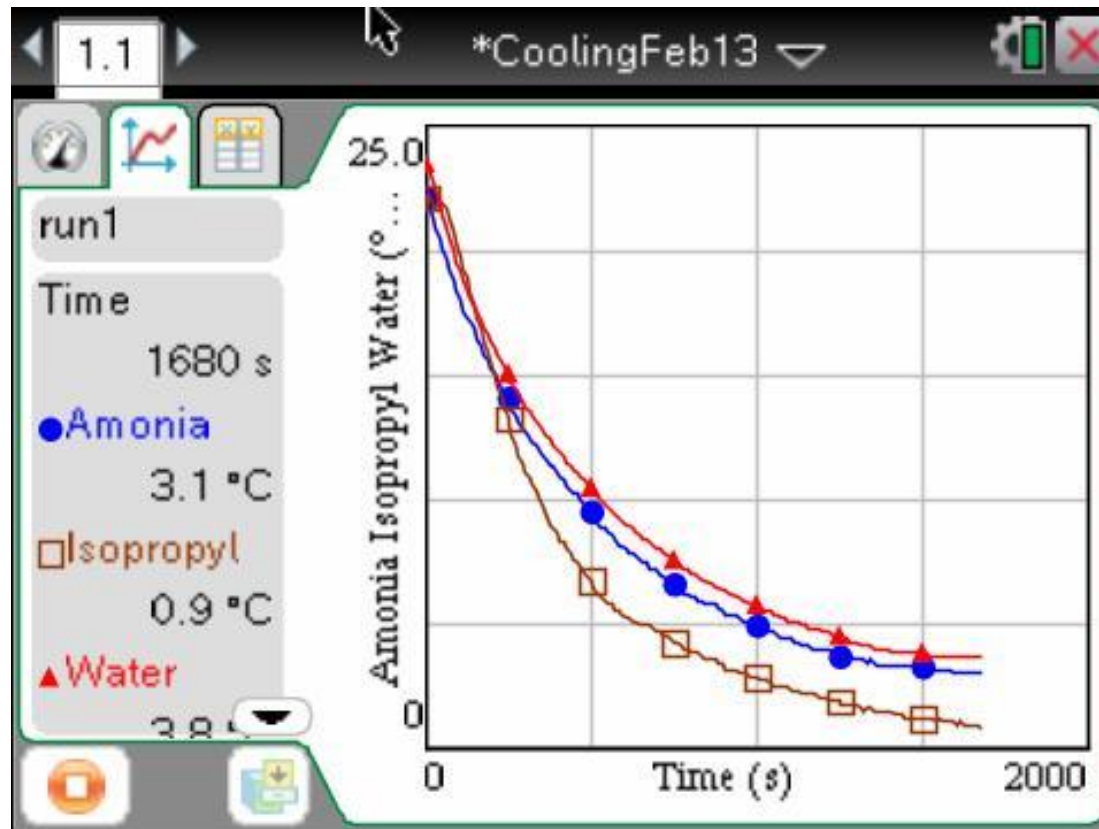

# Can Be Viewed By The Class

---

# Are Also Available Graphically

In 50 minutes some nice data

# And at the end as a spreadsheet

---

	run2		
	Time	Hexane	Isoprop
187	1860	2.8	
188	1870	2.9	
189	1880	2.8	
190	1890	2.8	
191	1900	2.8	

# Post-capture Analysis

---

- ▶ Discuss in class how this relates to our theoretical discussion of Newton's Law
- ▶ Assign groups to different liquids or data points
- ▶ Provide an outline of the write-up

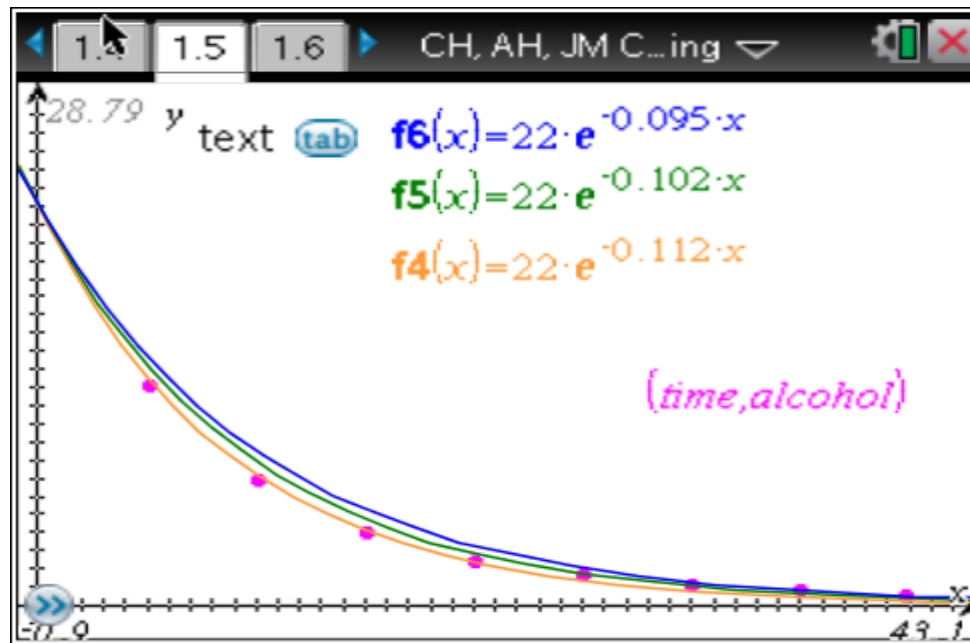

# Typical Outline Of The Write-Up

---

- ▶ Introduction (this is a writing project, so ask for readability)
- ▶ Background and raw data
- ▶ Three variations of the DE
  - ▶ Three different  $t_1$ 's
  - ▶ Complete derivations, with plots
  - ▶ TI's built-in exponential regression
- ▶ Discussion

# Some Results

All derived equations for tap water appear to be good predictors. This is because, when plotted, each equation generates a curve that most closely tracks the discrete data points. When compared to our raw data table, however, the equation  $f(1)$  appears to generate the best cooling constant to predict tap water's temperature at 39.75 minutes. At  $T(39.75)$  tap water was at  $1.0^\circ\text{C}$  minutes

# Suggestions

---

- ▶ Change liquids between semesters
- ▶ Talk to your chemists
  - ▶ Soap – useless
  - ▶ Cyclohexane – interesting behavior
- ▶ Watch over the students (some writing time in class)

# Other Experiments

---

- ▶ Logistic Growth (Bread mold)
- ▶ Fluid Flow (Torricelli)
- ▶ Parachute vs. gravity
